

For this project, I used agentic specifically to create my website and with my Difference-in-Differences analysis. For the website, I gave it my final paper as part of the query, so it had a lot of information about what I had done. I believe that this made it easier, and I had less follow-up questions or concerns as a result. The main piece it messed up was my project's question, which I then corrected.

For the DiD, I already knew the applicable datasets pretty well from my 01 notebook analysis. As a result, I was able to query it with things like "keep in mind that the column numbers are not all consistent, as the legacy definition of rape is removed between 2016 and 2017. This causes the number of all subsequent columns to shift." I also gave it the code that I used in the 01 notebook to clean the data, as I thought it would be helpful. At first, it tried to do the DiD with only rape data, using states with low reporting rates as the control. I found this to be flawed methodology, and suggested that it use the other violent crimes in the dataset as the control. After this, it went down a much stronger path methodologically.

In all, I have found that the more specific a query, the better the response. Agentic seems to work best when it's working on simpler tasks, not coming up with entire concepts or sections on its own.
